Submission St.Gallen / 20. Nov. 2023

ABSTRACT

A dataset containing information about 14'046 businesses operating in the Education Technology (EdTech) market was investigated regarding the adoption of Artificial Intelligence (AI). The ventures contained in the dataset could be assigned to 23 topics, however, none is labeled "AI". The keywords representing said topics mostly reflect the primary visions and customer segments. The analysis suggests that AI is only a tool to realize these visions, therefore about the operational dimension of the business model. The idea of AI-first EdTech companies does not appear in the self-description of ventures listed on CrunchBase. The logical conclusion of this first analysis is that AI is not the "hot" topic in EdTech, as it is not a topic at all. A binary classification was added to the dataset in the second analytical step. It confirmed that **Artificial Intelligence (AI) is not the current "hot" topic in EdTech**, as the distribution of AI companies regarding size, total funding, and age appears random. As the data revealed no trend, analyzing investor behavior regarding a trend-based bias linked to AI was made impossible. However, the temporal analysis using Kernel Density Estimates (KDE) on the topics resulting from the first step revealed additional insights linked to the wider field of emerging technologies: In the past Virtual Reality (VR) was a "hot" topic, explicitly referring to a specific technology, in the EdTech market. **The association with this "hot" topic influenced investor behavior negatively**, the ventures founded during the hype phase with growing interest in VR received less funding on average than both VR business across the entire dataset and the wider EdTech peer group founded within the same timeframe. This finding partly validates the concept of "smart money", as professional investors do not overinvest based on a trend-driven bias.

I INTRODUCTION

“Overall, a mere association with the Internet seems enough to provide a firm with a large and permanent value increase.”

(Cooper et al., 2001, p. 2386).

This surprising insight from researching the dot-com bubble of the early 2000s, seemingly running against conventional business logic, is the inspiration for this thesis. The underlying idea can be more broadly framed as exploring the relationship between topics and business valuation. The basic idea is to identify “hot” or “cold” topics. In scientific literature topics with growing interest, thus “hot” topics, are delimited by an increasing number of publications, whilst “cold” topics are the inverse. (Griffiths & Steyvers, 2004). This definition intended for scientific publications can be easily adapted for start-ups by replacing the number of articles mentioning a certain topic with the number of newly founded firms (self-)identifying with a topic employing their description. In the contemporary technological innovation landscape, perhaps no field garners as much attention and fascination as Artificial Intelligence (AI). The rise of AI technologies has been nothing short of meteoric, with its influence extending far beyond computer science to profoundly impact various aspects of our daily lives. Illustrative of this rise to prominence is the increased search interest for the term (Google, 2023). The Gartner EmTech Report is an annual publication from a leading technology consultancy, thus underpinning the relevance of the technology from a practitioner’s view. It lists multiple forms of AI in the adoption cycle. At the same time, the current version of the publication is also a warning of inflated expectations as most topics relating to AI are at the “Peak of Inflated Expectations”. (Gartner, 2023).

OpenAI, a leading player in the AI industry, has shattered records in terms of adoption speed, reaching 1 million users within a week (UBS, 2023). The pace at which OpenAI's technologies have been embraced is indicative of the fervent curiosity and eagerness of both individuals and organizations to harness the capabilities of AI for solving complex problems and driving innovation. This unprecedented adoption rate reflects not only the transformative potential of AI but also the compelling need for its integration across diverse sectors of society, including education.

In contrast to the beforementioned study tracking name changes referring to the internet in public markets (Cooper et al., 2001), this thesis narrows the scope to derive deep insights into Education Technology (EdTech) companies. Revisiting a concept already established more than 20 years ago is merited by the shift in hotly discussed technologies, today AI is what the internet once represented. As already touched upon AI is a rapidly growing field that has seen an influx of investment and innovation over the past decade. This deeply rooted analysis of a private market also incorporates emerging and less-known players in the domain. Leveraging machine learning, I also extend the body of analysis and aim to integrate the company description rather than solely their name to determine association with a topic. This shift in scope is made possible by two distinct advances in computing. Firstly, data availability has increased significantly, enabling an analysis of private markets. All major providers of private market data for Venture Capital (VC) have been founded after 2001. Their rise was significantly aided by the increased interest in private markets. (Retterath & Braun, 2020, p. 2). This thesis relies on CrunchBase as a data provider, as is considered reliable and accessible for researchers. Secondly, what must have seemed like an impossible amount of data to process in the early 2000's, is well within the possibilities of modern widely available computers and cloud infrastructure. The rise of cloud computing has revolutionized how businesses

and individuals access computing resources. At the heart of this development is Moore's Law, which approximates that the number of transistors on a microchip doubles every two years (Moore, 1998). This has allowed for the development of ever more powerful and efficient computing systems, which have made cloud computing possible. In turn, cloud computing has allowed for the creation of new applications and services that would have been impossible just a few years ago, making it an essential part of the modern technology landscape.

The described rise of new topics and tools culminates in the following research questions:

RQ1: Is Artificial Intelligence (AI) the current “hot” topic in EdTech?

RQ2: Does association with a “hot” topic influence investor behavior?

This thesis is structured as follows. Firstly, existing literature is condensed, and important terminology is explained. This is followed by the methodology part highlighting topic modeling (TM) and classification methods. As well as explaining data collection and treatment. The results part of this thesis reveals the following key insights regarding investor behavior in the EdTech market: With the research question in mind, it must be noted, that no topic is either directly labeled with AI or any closely related terminology. AI was thus not a “hot” topic as it was not a topic at all. TM revealed that in the past “hot” topics occurred, measured by the number of ventures created. However, there is no generalizable correlation between topics and funding, and there is also no correlation between AI companies and funding, independent of whether self-identified or ML-based classification is employed. The topics identified in company descriptions do not necessarily follow technological trends. They seem to mostly address the customer and their needs, based on the evaluation of the most informative words contained in each topic. Lastly, regulatory changes in major markets are also reflected in the TM outcomes.

2 THEORETICAL BACKGROUND

This chapter contains two major subchapters, each treating a fundamental theoretical field linked to this thesis. In order these fields are Education Technology (EdTech) and Investor Behavior. The first part describes the objects to which investors allocate funds, and the second part their approach to valuing said object.

2.1 EDUCATION TECHNOLOGY

EdTech, short for Educational Technology, refers to the use of technology and digital tools to enhance and support teaching and learning processes. EdTech, as understood in this thesis, encompasses a wide range of technologies and digital resources, including software, hardware, online platforms, and applications designed for educational purposes.

2.1.1 THE EDTECH MARKET

Education, a highly traditional industry, is currently experiencing a profound disruption driven by the forces of digitalization. This trend has been accelerated by the COVID-19 pandemic. (Gallagher & Palmer, 2020). On a global scale, almost immediately students had to switch from on-site to digital ways of learning, subverting long-established, traditional ways of teaching. EdTech has remained relevant ever since. (Lyons, 2017). The EdTech market has been experiencing strong growth with increased investments from venture capitalists as well as government initiatives aimed at promoting EdTech adoption in schools around the world. Driven by the underlying VC boom and the pandemic pushing education online, private investment in EdTech grew from 16.1 billion USD in 2020 to 20.8 billion USD in 2021. However, in 2022 the market started to cool a little with investments falling to 10.6 billion USD. The predictions for 2023

suggest total investments in the pre-pandemic range between 7 and 8.5 billion USD. (Whitford, 2023).

2.1.2 EMERGING BUSINESS MODELS

Whilst the market definition above clarifies the wider context a business operates in, it is not specific enough to distinguish between businesses. In the field of business strategy and innovation, a business model serves as a fundamental framework for answering critical questions that underpin the essence of a business. Gassmann, Frankenberger, and Csik's (2014) framework, which organizes a business model into four dimensions, forms a cornerstone of this thesis. Their four dimensions encompass the "WHO," "WHAT," "HOW," and "WHY" aspects of a business model, collectively providing a comprehensive view of the business's structure and functionality. The "WHO" dimension pertains to the identification of the target customer group, a fundamental consideration for any business model. The "WHAT" dimension revolves around the value proposition, delineating what the business offers and what the customer values. To execute these value propositions, the "HOW" dimension emphasizes the need for mastery of various processes, activities, resources, and capabilities. Lastly, the "WHY" dimension delves into the financial viability of the business model, encompassing aspects like cost structures and revenue mechanisms. This holistic framework serves as a vital tool in dissecting, understanding, and innovating business models, guiding the strategic decisions and value creation efforts of organizations. (Gassmann et al., 2014, pp. 8–12, 2016, pp. 19–22).

An important sub-category of businesses popularizing emerging technologies is start-ups. Whilst there are numerous definitions of start-ups to be found, in this thesis a relatively simple definition is chosen: All firms younger than 2 Years that did not form through M&A are considered a start-up. Besides its simplicity, the main advantage of this version is the overlap with the OECD (Criscuolo et al., 2014, p. 19), thus enabling comparison with established economic facts.

Furthermore, this definition facilitates a simple temporal subsampling when analyzing the dataset later in this thesis.

2.1.3 ADOPTION OF ARTIFICIAL INTELLIGENCE

AI in the context of this thesis is treated in depth for two reasons. It appears as the most probable “hot” topic to a casual observer, and it underpins the NLP analysis from a technological standpoint. All information about the use of AI as a tool in this thesis can be found in Chapter 3.2.

The term AI is a colloquial umbrella term masking a wealth of different technologies and concepts. Given the very complex nature of the underlying technology, I introduce the fundamental pillars of AI and related concepts in the following chapter. In this chapter first, a short overview of the philosophical concepts underpinning AI is given, followed by an overview of the technological evolution and lastly, an assessment of the impact on the EdTech sector is provided.

The creation of (artificial) humans is by no means a new topic of interest, virtually all civilizations have their legend or religious origin story of humans. Be it the creation of man on the 6th day in the Abrahamic religions or Prometheus, who shaped man out of mud, and was aided by Athena, who breathed life into the clay figure.

The Turing Test, originally named “the imitation game”, can be considered the modern focal point of this line of thought asking: What constitutes a human being? Named after his creator, who also created the Enigma decryption machine, which is widely accepted as one of the crucial predecessors to modern computers, the Turing Test remains relevant to the contemporary discussion of computing. In simple terms, the test declares artificial intelligence, in the terminology of the original, thinking machines, as equal to human intelligence if

you can converse with it without noticing the otherness of the machine. (Oppy & Dowe, 2021; Turing, 1950).

Modern computer technology is on the verge of crossing the boundaries set forth by Turing. In a comprehensive gamified online study¹ modeled after Turing's thought experiment involving 1.5 million users participating in anonymous two-minute chat sessions, a fascinating pattern emerged. Participants would either chat with a fellow participant or with LLM-enabled chatbots, they could correctly identify the identity of their chat partners as either human or non-human in only 68% of the games. The results not only underscore the inherent difficulty in gauging the authenticity of online interactions but also reveal the potential limitations of human intuition when confronted with increasingly sophisticated AI technologies. The lines between human and artificial intelligence seem increasingly blurry. (Jannai et al., 2023).

However, there are challenges to the validity of the Turing test as a delimiter between human and artificial intelligence. Chief among them is the Chinese Room Argument, standing as one of the most influential and contentious thought experiments in the philosophy of mind and artificial intelligence. The thought experiment was first published in a 1980 article titled "minds, brains, and programs" by American philosopher John Searle.

In essence, Searle challenges the notion that a computer program can possess genuine understanding or consciousness. He presents a scenario in which a person, who does not understand Chinese, is situated in a room with a set of instructions for manipulating Chinese symbols. Outsiders pass questions written in Chinese into the room, and the person, following the instructions, generates responses that appear as if they understand Chinese.

¹ <https://www.humanornot.ai/>

Searle's argument hinges on the assertion that merely manipulating symbols according to a set of rules does not constitute genuine understanding. He contends that, despite appearances, the person in the room does not comprehend the Chinese language any more than a computer running a program does. This thought experiment underscores Searle's belief that syntax, thus the manipulation of symbols, alone is insufficient for semantics. (Searle, 1980).

Critics and proponents alike engage in ongoing debate over the Chinese Room Argument's validity and implications for artificial intelligence and the philosophy of consciousness. While it does not provide a definitive conclusion, Searle's argument has undeniably sparked significant discourse and remains a touchstone in these fields, challenging us to grapple with the fundamental question of what it means to truly understand and think. (Cole, 2023).

The opinions in the academic discourse concerning consciousness range, in short, from positing it as the driving force explaining even the very laws of nature, the so-called Panpsychism (Goff, 2020) to declaring it a mere illusion, suggesting that the human brain is incapable of understanding its inner workings and thus infers that some “magical” ingredient, in this case, consciousness, must exist although it does not (Dennett, 2016).

For Chomsky et al. (2023) one of the decisive factors in considering AI sub-par to human intelligence is that although it appears capable of sophisticated thought and language, it shows the moral indifference born of unintelligence. The memory-based and statistical nature of AI means that it lacks another hallmark of intelligence too: The ability to create ideas and theories with universal reach. Furthermore, they argue that contemporary AI systems are far from rivaling humans in efficiency, as human minds can easily create explanations without the need to infer brute correlations among data points.

Others find a convergence of Brains and Algorithms, thus implying that humans and machines are not dissimilar in their reasoning. (Caucheteux & King, 2022).

However, this convergence is not a given for all systems, as other researchers describe the comparison resulting in stark contrast: “the non-human-like nature of the knowledge learned by the network.” became obvious (Mitchell & Bowers, 2020, p. 5147).

The term Artificial Intelligence was coined in a research proposal by McCarthy, Minsky, Rochester, and Shannon (1955). Minsky would later become one of the leading thinkers in the field. Early AI research included the perceptron: a rudimentary image classifier hailed in news articles as an artificial brain (Mason et al., 1958; Rosenblatt, 1958). The idea of imitating the human brain is pervasive in the history of AI. The fundamental idea to imitate the human brain and create sub-units of decision-making would later culminate in the development of neural networks. The early enthusiasm for the topic however faded and gave way to the so-called “AI winter”, a period during which progress stalled. Even decades after the initial interest in the topic, research, such as early advances in self-driving vehicles, was severely limited by the computational power of its time (Pomerleau, 1988).

The advances of modern AI, the so-called “AI spring”, start with the advent of big data. Independently, but importantly contemporary to the rise of Big Data, the idea of borrowing structurally from biology, especially the human brain, was reinvigorated, and Neural Networks emerged.

An early driver of the new age of AI was the ImageNet challenge. The challenge makes use of big data, providing a big collection of labeled images to train and test image classification algorithms. The basic concept was to create an algorithm that could analyze a random picture and correctly classify whatever it was depicting (Russakovsky, Deng et al., 2015).

The ImageNet challenge culminated in the emergence of an algorithm named AlexNet as the ultimate victor. AlexNet's triumph in the competition marked a significant turning point in the domain of image classification and recognition.

This pioneering convolutional neural network, designed by Alex Krizhevsky, Ilya Sutskever, and Geoffrey Hinton, demonstrated an unprecedented breakthrough in the ability to recognize objects and images within vast datasets. Its success was a result of several innovative elements, chief among them the adoption of GPU-based parallel computing to expedite model training. AlexNet's remarkable accuracy and efficiency in processing vast image databases not only secured its victory in the ImageNet challenge but also set the stage for the subsequent deep learning revolution. (Krizhevsky et al., 2017).

The impact of AlexNet reverberated across various applications, including image recognition, natural language processing, and autonomous systems, reshaping the landscape of artificial intelligence and establishing deep learning as a dominant paradigm in the AI community.

The introduction of the transformer architecture marked another seminal breakthrough in the field of AI. The transformer model revolutionized the treatment of sequential data, particularly in tasks involving language understanding and generation. This innovative architecture introduced a mechanism based on self-attention. Self-attention enabled the model to weigh the importance of different words in a sentence, allowing it to capture complex relationships and long-range dependencies in the data. (Vaswani et al., 2017).

The introduction of the transformer architecture not only significantly improved the performance of various NLP tasks but also paved the way for the development of large pre-trained language models like BERT, GPT, and their derivatives, which have become the backbone of state-of-the-art models with enormous sizes in terms of parameters (Sevilla et al., 2022; Thompson, 2021).

AI-driven applications have become an integral part of our digital landscape, transforming the way humans interact with technology in virtually all industries (Chui et al., 2018). ChatGPT's rapid rise is emblematic of the increasing role AI

plays in our daily lives, as users embrace AI for a multitude of applications, from virtual assistants to content generation. (UBS, 2023).

The advent of AI has undeniably ushered in a multitude of opportunities, but companies face diverse hurdles in realizing efficiency and efficacy gains (Haefner et al., 2023; Raisch & Krakowski, 2021). Furthermore, AI is also riddled with controversies and social issues. A prominent concern within the realm of AI is the manifestation of bias in AI systems. In one striking example, Google misclassified pictures of black people as gorillas (Barr, 2015).

Bias can creep into AI systems through various means, including biased training data, algorithmic biases, and biased decision-making processes. These biases can lead to discriminatory outcomes, unequal access, and perpetuation of societal inequalities. (Cowgill, 2019).

Furthermore, the proliferation of AI carries wide-ranging implications for the workforce. The deployment of AI technologies has the potential to transform industries and job landscapes, posing challenges in terms of workforce adaptability and implications for overall employment. (Berg et al., 2018; Brynjolfsson & McAfee, 2017; Brynjolfsson & Mitchell, 2017).

Besides social downsides, there is also the fear of dual use of AI, as it is finding application both as a military and civilian technology. In one example a team of researchers normally researching molecules for pharmaceutical use managed to generate the structure of 40,000 poisons, amongst them the chemical agent VX, which finds use as a chemical weapon. This sinister aim was achieved by the relatively simple reversal of one variable in their otherwise civilian algorithm serving medical research. (Urbina et al., 2022).

More direct military applications include target identification and designation, depending on military doctrine even probability-based life/death decisions are gaining prominence (Michel, 2023).

Not only are the future implications of the technology unclear but also the evolution of models itself is unclear. The evolution of AI models, particularly exemplified by ChatGPT, has introduced a level of unpredictability in their behavior. Small, seemingly inconsequential modifications to input can yield unexpected outcomes, showcasing the intricacies of model behavior and the potential for inconsistencies. ChatGPT has displayed shifts in its outputs over time, emphasizing the challenge of ensuring reliable and consistent performance. (Chen et al., 2023).

Lastly the exponential increase in transistor density, colloquially called Moore's Law, an underlying driver of the current "AI spring" is potentially reaching its end as the physical components of computers are quickly nearing the atomic limit, the theoretical minimum size of one atom to conduct electric current (Waldrop, 2016). This implies that without advances in quantum computing, further advances in AI based on increasing model size will come to an end as the physical computer parts are no longer enabling this strategy for model improvement.

The range of technologies that constitute AI includes rule-based systems, classic machine learning, and representation learning (Goodfellow et al., 2016). Other definitions and terminology exist, regularly classic machine learning is referred to as supervised (machine) learning, and representation learning is referred to as unsupervised (machine) learning.

The working definition of AI for this thesis is wide. This means that all forms of "algorithmic intelligence" mentioned above are considered.

This has primarily a practical reason: the differentiation into more fine-grained categories requires a huge amount of data, with precise tags. This kind of dataset is not easily available. The pre-existing dataset that focuses on identifying AI in a management science context uses a high-level definition (Miric et al., 2023).

The education sector, a historically conventional industry, is undergoing a substantial transformation, largely catalyzed by the pervasive influence of digitalization. The COVID-19 pandemic accelerated this shift, as students worldwide swiftly transitioned from traditional, in-person learning to digital modalities. This abrupt change challenged established teaching methodologies and highlighted the significance of EdTech. The enduring relevance of digital solutions in education signifies a lasting impact on how education is delivered and accessed and the continued evolution of learning paradigms in response to changing global dynamics. signifying a lasting impact on how education is delivered and accessed. (Gallagher & Palmer, 2020)

At the heart of this transformation lies the fact that education, in its various forms, fundamentally revolves around the effective processing of information. Information processing is a forte of AI technologies. This intersection underscores a pivotal convergence, as AI can significantly augment and innovate two core functions of education: teaching and research. In both domains, the assimilation, analysis, and communication of information play pivotal roles. The application of AI in education not only holds the promise of enhancing instructional techniques and personalizing learning experiences but also revolutionizing the research landscape by enabling novel insights through advanced data analysis. This paper delves into the evolving relationship between AI and education, exploring how AI's information-processing capabilities are reshaping the educational landscape and propelling us into a new era of learning and research. (Gassmann et al., 2023)

The relevance of the EdTech sector in combination with AI is driven from both sides, explained Meta's Head of AI Jerome Pesenti on the Podcast *Weights & Biases*: The AI community sees education as a potential market and the education sector sees AI as a potential new tool. (Fields & Pan, 2022, min. 35:55-40:15).

Writing, especially in the form of essays, is at the core of traditional education. A field substantially impacted by modern NLP systems. Universities need to overthink how they award degrees, as it can be reasonably expected that a substantial part of the average student workload can be automated by systems like ChatGPT. (Marche, 2022).

The abilities of these contemporary language processing systems are further illustrated by the fact that ChatGPT passed, amongst others, law school exams in blind grading of four tests, consisting of 95 multiple-choice-questions and 12 essay questions. The AI achieved a grade of C+, ergo below average but passing (Choi et al., 2023). These results raise obvious questions of fairness and justification of grades awarded to students.

In another Experiment at Wharton ChatGPT fared well too. The key takeaways include the advice of banning AI tools when testing foundational knowledge, raising awareness for its limitations, and deploying the technology to improve the productivity of the teaching process (Terwiesch, 2023).

2.2 INVESTOR BEHAVIOR

Establishing a business encompasses the pursuit of opportunities, the allocation of resources, and the creation of value. To bring their visions to fruition entrepreneurs need funding. While a business fulfills different needs of different stakeholders, this thesis focuses on its role as an investment object. The previous chapter therefore describes the target, while this chapter will discuss investments as an activity.

On one hand, the essential theories underpinning company valuations are discussed. On the other hand, the evolution of behavioral finance and investor psychology is laid out.

2.2.1 BUSINESS VALUATION AND INVESTMENT BIASES

In general, new ventures are traded on private markets (venture capital) and not on public markets (stock exchanges), thus market prices are highly dependent on the valuation of a few involved parties. In practice, business leaders mostly rely on the Discounted Cash Flow (DCF) method of valuing companies or projects. The method consists of two key components: the expected cash flows and the discount rate. It is thus future-oriented and introspective. It aims to factor in opportunity costs through the use of the discount rate, leading to the estimate of the present value of each project or enterprise (Sahlmann & Scherlis, 2009; Stevenson et al., 1999).

It is often accompanied by multiples as a secondary method, whenever data from financial markets are available the P/E multiple is the most popular one. The multiples approach is based on the known values of industry peers, thus reflecting an estimate based on external, market-based valuations. This latter method is highly dependent on the selection of companies included in the peer group. (Berndt et al., 2014; Koller et al., 2005).

Start-up valuation is more complex than valuing long-standing, publicly traded firms. This complexity is mainly driven by a lack of historical, reliable financial data from within the venture. There is no established baseline of financial performance to anchor growth projections. The valuation is thus often based on the potential and ability of the team rather than quantifiable financial data. These assumptions are then codified in business plans. A practical example features the T2D3 (triple, triple, double, double, double) growth model. These very rough growth estimates illustrate again, that valuation for start-ups is mostly about agreeing on a price range rather than precise calculations. (Cavalry Ventures, 2022). Additionally, there is a specialty in valuing AI companies that is noteworthy in the context of this thesis: Competitive advantage and thus

valuation is driven by the amount and quality of data an AI start-up controls (Bessen et al., 2022).

The intersection of cognition and management research provides a rich and diverse landscape for exploring how individuals and organizations perceive and make sense of their environments. At the core of this research lies the concept of mental frameworks, serving as reference points that structure information and guide decision-making processes. These cognitive representations that individuals have developed from past experiences are used to navigate future challenges. The term dominant logic encapsulates how individuals and organizations conceptualize their industry, operationalize their past successes, and shape their decision-making processes. It essentially serves as a prevailing mindset that influences not only the strategies formulated but also the means employed to achieve goals. (Gassmann et al., 2016, pp. 50–54; Prahalad & Bettis, 1986).

The Efficient Markets theory enjoyed its heyday in the academic world during the 1970s, asserting that financial markets fully incorporate all available information, making it impossible to consistently outperform the market. However, this theory was progressively undermined by a series of discoveries in the 1980s, revealing market anomalies and evidence of unexpected volatility in returns, paving the way for the emergence of behavioral finance. Since the 1990s, behavioral finance has flourished as a subfield, focusing on understanding how psychological factors and irrational behaviors influence financial decision-making. Notable developments include feedback theories that elucidate market dynamics, models that explore the interaction between informed investors and ordinary participants, and extensive research on sophisticated investors in financial markets, also known as "smart money". This paradigm shift towards acknowledging the complexities of investor behavior and market dynamics has reshaped our understanding of financial markets and paved the way for more

holistic and inclusive theories that encapsulate both rational and irrational elements in decision-making. (Shiller, 2003).

Perception biases play a central role in shaping financial decisions. A wide array of potential biases is described. The findings indicate that investment biases may be inherent expressions of deeply rooted, evolutionarily aspects of human behavior. (Heath & Tversky, 1991; Kahneman & Riepe, 1998; Kahneman & Tversky, 1979; Tversky & Kahneman, 1974, 1992)

The most relevant of these biases in the context of this thesis is the concept of conformity bias, sometimes also referred to as "Group Think". This cognitive bias potentially compels investors to react to prevailing market trends or consensus opinions, leading to herding behavior. This phenomenon has also been described as the "overextrapolation of trends" (Alti & Tetlock, 2014). The presence of conformity bias can have profound implications for financial markets, as it can drive asset prices away from their intrinsic values, contribute to asset bubbles, and amplify market volatility. (Moscovici & Faucheux, 1972).

Important to note in the context of this thesis is, that individuals who have accumulated experience in finance exhibit a reduced inclination toward these biases (Cronqvist & Siegel, 2014).

This thesis tries to understand financial decision-making, with a specific focus on trend-driven biases, analyzing their manifestation in the context of investments in the EdTech market. Understanding these biases is pivotal in improving investment strategies or advancing fundraising strategies.

2.2.2 MEASURING TRENDS AND INVESTOR BEHAVIOR

In simplified terms, this thesis investigates whether investors make good decisions or if their perception is skewed by the adoption of AI.

The primary object of analysis is the total funding a venture receives, it is the most direct expression and quantifiable measure of investor behavior in the

dataset. It is measured in USD and indicates how attractive a business idea is to investors.

Adapting the definition of Blei et al. (2003), which suggests considering a topic “hot” in science when there is growth in the number of published contributions to a topic, for the VC context means, that a “hot” topic is delimited by the relative increase in new ventures created assigned to a topic. The same data pattern is classified as “hype” elsewhere (Buck et al., 1998, p. 65).

Combining these two ideas means first establishing topics and trends within the dataset. By analyzing the sensitivity of investors to the ventures within a “hot” topic period I establish a measure for the quality of investment decisions. This is effectuated by contrasting the average investments during and outside the “hot” phase.

The idea is best exemplified by the findings of Cooper, Dimitrov, and Rau (2001) already mentioned in the introduction: A mere affiliation with the internet through a simple name change significantly enhanced a firm’s value during the late 1990s. This association, regardless of the extent of actual internet utilization in the firm’s operations, triggered a substantial and enduring increase in the firm’s stock price. This phenomenon underscores the power of trend-based biases regarding business valuation.

3 METHODOLOGY

Conceptually I aim to find insights in a pre-existing dataset. Traditionally management science is theory driven and subsequent research is undertaken to prove or disprove the theory. In this case, the data is used for fact-finding and theory validation in a specific sector. The following chapters shed light on the data collected and the tools used to evaluate said data. For further technical information please consult the provided iPython Notebooks (.ipynb-files) containing the original code².

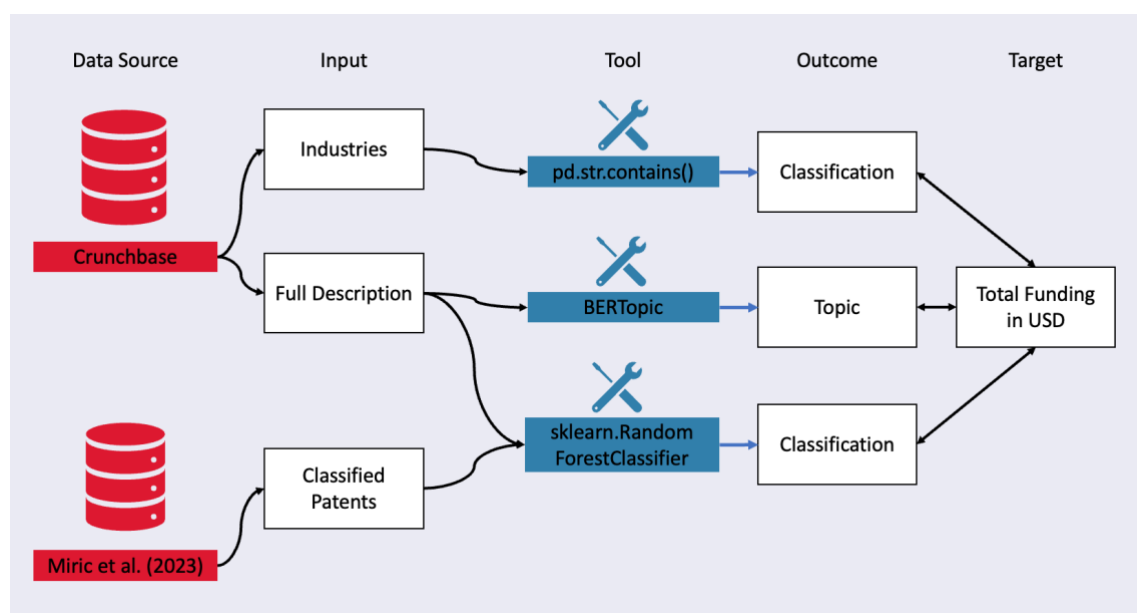

Figure 1 Research Design

In terms of methodology, this thesis employs topic modeling and classification algorithms on company descriptions to recognize their connections with AI technology. The topic modeling is done using BERTopic, thus employing a purpose-built library utilizing a modern Large Language Model (LLM). The classification follows a two-pronged approach. On one side the self-declared industry-tag is analyzed. On the other hand, Machine Learning (ML) is

² See Appendix or <https://github.com/MarioMuehlematter/Education.ai>

employed. The company descriptions are reduced to a Bag-of-Words (BoW), which in turn is then classified as containing AI-related words, word fragments or word stems. This is done following the example of Miric et al. (2023), who identified Random Forest classification (RFC) as the most promising approach for management science. With regards to data quality and completeness of the dataset at hand, total funding was focused upon. Survival and the number of employees were considered as well, though they were not treated in depth and only used to assure data integrity and quality.

3.1 DATA COLLECTION AND PRE-PROCESSING

In the following chapter, the process of collecting and subsequently curating the necessary data is described. Additionally, some high-level insights into the obtained dataset are described. The dataset was prepared with a focus on enabling NLP later in mind.

3.1.1 DATASET INFORMATION

The dataset was extracted from CrunchBase (CB). The investor platform features an extensive collection of data that is also valuable and useful for science. The data on CB is considered reliable. It is one of the two dominant VC databases for academic research, the other major player being Pitchbook. Together they provide the foundational data for approximately 75% of VC-related publications after 2015 (Retterath & Braun, 2020, p. 7). In 2017 there were 90 articles and papers that relied on CB, most were recent, and the first one dates back to 2009 (Dalle et al., 2017, p.16).

The information contained in CB is dominated by the American start-up ecosystem, the clear majority of listed firms have less than 50 employees (FTE) and are US-based (Dalle et al., 2017, pp. 8–11).

Other known biases in CB data include a positive selection bias, as entrepreneurs with high-quality ventures have an incentive to increase their visibility and send signals to potential investors subsequently increasing the value of their shares. Despite these limitations, CB offers the best information regarding financing rounds and total funds raised (Retterath & Braun, 2020, pp. 3–4).

Dalle et al. (2017, pp.16–18) note that there is a high variety of research questions addressed by using CB data. They further identified four research clusters based on journals, the main areas of research interest of said publications were: Management, Green Innovation, Technology, and Small Business. The third group, Technology, applies to this paper.

There are also two other clusters of research, not defined by publication outlet but by topic, that are relevant to this master's thesis. The first group concerns research based on CB data that analyses investor behavior (Liang & Yuan, 2016; Zeng et al., 2016; Zhong et al., 2018). The second group consists of examples of other authors using CB and Topic Modelling (Chae & Olson, 2021; Shi et al., 2016).

The earliest founding date in the dataset underlying this master's thesis is the 1st of January 2009 and the data collection was cut off at the end of 2022. The initial dataset exported from CB contained 29,346 company profiles, with 112 columns each. In pre-processing companies whose descriptions are too short (word counts <30) to be useful for topic modeling were excluded, following the example of Chae & Olson (2021). Virtually all entries in the simple "Description" column of the dataset are too short, according to established data science practice. Therefore the "Full Description" column was used for further processing. 14,046 entries and 1,225,060 words remained in the resulting dataset used for analysis. The company descriptions therein contain 87.2 words on average.

Each company profile of the final dataset had 112 columns, ranging from "Organization Name URL" to "Aberdeen - IT Spend Currency (in USD)", the

completeness of these entries varies widely, a full list of column names is available in the appendix. Naturally not all 112 fields were considered in the analysis, I actively used the following information: Full Description, Founded Date, Headquarters Location, Number of Employees, Total Funding Amount Currency (in USD), and Operating Status.

Lastly, a high-level insight: the mean total funding amount of the ventures contained in the dataset was 16,354,648 USD.

3.1.2 DATA INTEGRITY AND QUALITY

Previously I established that CB is considered a relatively reliable data source. It was also noted that certain biases are usually present. These established biases were controlled for in this thesis.

Firstly, when analyzing the number of ventures per country of origin, the focus on the US start-up scene is confirmed (see Fig. 2). It is noteworthy, that the top 10 countries of origin also contain relatively small countries like Switzerland, The Netherlands and Israel, all nations are also considered very innovative by the World Intellectual Property Organization (WIPO, 2022). However, other very innovative countries (e.g. Sweden) are missing from the most prevalent countries of origin in the dataset.

Figure 2 Number of Ventures per Country of Origin (Top 10)

(Note: 14004 out of 14046 entries contained information on location)

Striking is the contrast between the two most populous countries on earth, whilst almost naturally both China and India make the top 10, India is home to 1951 ventures while China only accommodates 314 firms of the dataset. The data offers no direct explanation of this discrepancy, it is plausible that Chinese entrepreneurs might simply favor different data providers.

Furthermore, the British (GBR) are either outcompeting their European counterparts of France, Germany, and Spain (FRA, GER, ESP) by 4x or there is a bias due to language or regional preference of VC data provider.

Another insight from the literature could be confirmed for the dataset: 87.6% of ventures had 50 or fewer employees (Note: 13248 out of 14046 entries contained information on headcount).

In conclusion, these outputs indicate that the findings of Dalle et al. (2017) are upheld for this EdTech-focused dataset. Company data provided by the CB database remain mostly US-based and small (<50 FTE).

The survival rate, as a secondary indicator, reflects the particularities of the start-up environment. While failures of established, publicly traded corporations are relatively rare, start-ups fail often. (Bureau of Labor Statistics, 2023; Gyeonggi Northern Chamber of Commerce and Industry, 2021). It makes therefore sense to measure the survival rate. Higher survivability does not directly indicate that a certain group of start-ups is more profitable but could also be driven by a higher willingness of investors to finance the losses³ of a group. To ensure optimal transferability and enable an insightful comparison this thesis appropriates the OECD definition of survival rates: *“The number of n-year survival enterprises for a particular year t refers to the number of enterprises which had at least one employee for the first time in year t-n and remained active in year t. This definition of survival excludes cases in which enterprises merge or are taken over by an existing enterprise in year t-n. The employer enterprise survival rate in sector (class size) x measures the number of enterprises of a specific birth cohort in sector (size class) x that have survived over different years. the n-year employer enterprise survival rate for a reference year t is calculated as the number of n-year survival enterprises as a percentage of all enterprises that reported at least one employee for the first time in year t-n. the share of n-year-old employer enterprises for a particular year t refers to the number of n-year survival enterprises as a percentage of the total employer enterprise population in year t.”* (OECD, 2017, p. 88). The survival rate offers a valuable checkpoint for data quality and reliability as it enables a comparison between the dataset and the wider economy. Retterath and Braun (2020, p.3) note that “VC databases should be more likely to collect self-reported information on higher-quality firms, resulting in a positive selection bias”. To control for said bias, additional data from the OECD and the USA, as it is the most common country of origin in the

³ Start-ups often use the terms cash-burn and runway, cash-burn being the operational loss per period and runway being the time until new financing is necessary or else the company defaults.

dataset, is introduced. The first is provided by Gyeonggi Northern Chamber of Commerce and Industry (2021), the latter sourced from the Bureau of Labor Statistics (2023). The additional data reveals, that the positive selection bias suggested in Reterath & Braun (2020) is present (see Fig 3). The discrepancy in the survival rate of firms is stark from the beginning to the end. This finding indicates that the dataset is not fully representative of the wider American or Western economy.

Figure 3 Survival Rate Comparison

Additionally, the US survival rates show the “COVID-Freeze” in bankruptcy, whilst the OECD values used as baseline are older and do not feature the pandemic bump, caused by government stimuli. The pandemic might also partially explain the ultra-high survival rate in the EdTech dataset.

3.2 DATA PROCESSING

The following chapter recounts the steps involved in processing the data with two different methods of Natural Language Processing (NLP). By leveraging the strengths of each method, namely Topic Modeling (TM) and classification enabled by Machine Learning (ML), the understanding of the data was deepened. The aim was to uncover latent patterns, relationships, and classifications that might remain elusive when relying on a single technique. This dual-method approach not only contributes to the comprehensiveness and robustness of my analysis but also highlights the versatility of NLP as an indispensable tool in the realm of data-driven research. Working with natural language data requires a common understanding of the following terms:

- *A word is the basic unit of discrete data, defined to be an item from a vocabulary.*
- *A document is a sequence of words.*
- *A corpus is a collection of documents.*

The definitions above are adopted from Blei et al. (2003, p. 995), with only minor simplifications.

3.2.1 STEP 1: TOPIC MODELING (BERTOPIC)

The first analysis in this thesis uses TM in conjunction with the founding date of each firm to identify “hot” or “cold” topics. Griffiths and Steyvers (2004) define, for an academic setting, topics gaining prominence based on the increasing number of publications during a period as “hot”, the inverse is considered “cold”.

This idea holds substantial potential for adaptation within the context of start-up ecosystems. This is achieved by substituting the count of scholarly articles with the number of newly founded firms self-identifying with specific topics. In this context, “hot” topics signify areas of entrepreneurial interest and activity experiencing growth and innovation, while “cold” topics represent the converse,

characterized by waning entrepreneurial engagement. By leveraging this concept, valuable insights into the evolution of the start-up landscape are gained. Helping to identify areas of opportunity, anticipate market shifts, and guide strategic decision-making.

In 2003 a paper established the origins of TM in the modern computational sense, making use of the Latent Dirichlet Allocation (LDA) algorithm (Blei et al., 2003). However, technology has evolved since then. Based on transformer technology Large Language Models (LLM) have emerged (Vaswani et al., 2017). These models enable more sophisticated algorithmic text analysis.

Currently, there is a wide range of LLMs, based on different model architectures and training data, available for research purposes. The best-known architectures include GPT, deployed by OpenAI in their own ChatGPT as well as Microsoft's Bing AI, Llama researched and published by Meta, and PaLM powering Google's Bard AI. (Thompson, 2021).

Whilst being the sub-part subject to the most dynamic change at the moment, the TM methodology used in this thesis consists of more than an LLM. To secure a stable and reliable outcome the BERTopic Python library was used (Grootendorst, 2022). The architecture of said analysis tool is modular. The tech stack, meaning the modules utilized in this thesis were as follows:

This thesis makes use of the language representation model BERT (standing for Bidirectional Encoder Representations from Transformers). BERT is able to successfully tackle a broad range of NLP tasks, whilst remaining conceptually relatively simple and comprehensible (Devlin et al., 2019). Derivatives of the original BERT, remain at the cutting edge of technological development, measured by the GLUE benchmark (gluebenchmark.com, 2023; Wang et al., 2018). The exact variant used in the tech stack for TM is called SBERT (Reimers & Gurevych, 2019). This model is used to transform the text data into a mathematical vector representation.

The corpus-level multi-dimensional embeddings created using SBERT, are subsequently reduced using UMAP (standing for Uniform Manifold Approximation and Projection). This non-linear technique is distinguished by its ease of use and speed (McInnes et al., 2018).

Once the embeddings have been reduced, the next critical step in data analysis involves clustering. To achieve this, the power of HDBSCAN, a density-based clustering technique, was harnessed. Unlike traditional clustering methods, it is adept at identifying clusters of various shapes and excels in pinpointing outliers within the data. Consequently, this approach promises to enhance the quality of our resultant topic representation by minimizing noise. By allowing the data to self-organize into clusters based on density, HDBSCAN facilitates a more accurate and nuanced classification of documents. (McInnes et al., 2017).

After the documents are clustered, another proven technology, which also underpins modern Internet search engines, is applied to the corpus. Taking regress to an idea originally proposed by Spärck Jones (1972), TF-IDF (standing for term frequency-inverse document frequency) measures the importance of a word to a document in a corpus, adjusted for the fact that some words appear more frequently in general. TF-IDF is a well-established method for assessing word importance across a set of documents. It provides valuable insights into the relative significance of words in the context of the entire corpus. (Blei et al., 2003, pp. 993–994).

The BERTopic library uses this established approach innovatively by treating all documents within a specific cluster as a single corpus. By doing so and then applying TF-IDF, importance scores for words within that cluster are obtained. The rationale behind this method is that the more important a word is within a cluster, the more representative it is of the underlying topic encapsulated by that cluster. In essence, this approach enables the extraction of the most representative words per cluster, yielding concise and descriptive topics. This novel TF-IDF

application distills meaningful information and topic descriptions from complex document collections. (Grootendorst, 2022).

To summarize the process at a high level: So-called tokens (word fragments) are extracted from the analyzed text. Words are turned into number representations in that way and the resulting vectors are then compared to each other to build clusters. Reversing these clusters back to words, topics become evident. Once the topics are assigned to each dataset entry, adding the temporal component to the analysis is simple, as the date variable present in the original dataset can be used.

3.2.2 STEP 2: CLASSIFICATION USING SUPERVISED LEARNING

The second Natural Language Processing (NLP) technique employed in analyzing the dataset for this thesis was a form of supervised machine learning. This classification approach promised to offer a deeper and more nuanced perspective on the complex phenomena under investigation. This technology focuses on word-level analysis. It tries to extract informative fragments from the tokenized text, thus is a different approach to NLP entirely in comparison with the methods described in chpt. 3.2.1.

Following an existing example (Miric et al., 2023), the process of applying a Random Forest classifier (RFC) consists of multiple steps, as it is a form of supervised machine learning the model needs training before applying it. The training consists of tokenizing the text, then vectorizing these tokens, and assigning the known binary classification to the corresponding vector spaces. When applying the previously trained classifier to the CB data the tokenization and vectorization steps are repeated, and the binary classification is inferred based on the training dataset.

The tokenizing step is done using existing utilities contained in the Python-libraries nltk (Bird et al., 2009) and Genism (Řehůřek & Sojka, 2010). The process of extracting tokens from words results in a Bag of Words (BoW) containing word

fragments. In the same process step, so-called stopwords (a collection of words that usually contain no meaning, e.g. the words “is” and “the”) are removed.

The BoW is then vectorized, ergo transformed into a numeric representation, by applying the “TfidfVectorizer” contained in the Scikit-learn library (Pedregosa et al., 2011). The Python implementation of the untrained RFC model, originally conceived by Breiman (2001), can also be found in the same library.

The Random Forest algorithm is a versatile meta-estimator. It operates by constructing an ensemble of decision tree classifiers on diverse sub-samples of the dataset. The fundamental principle guiding this approach is that by amalgamating the outputs of multiple decision trees, the predictive accuracy of the model can be enhanced while simultaneously mitigating the risk of overfitting, a common challenge in machine learning. It ensures robust classification outcomes. (Pedregosa et al., 2011).

The final training step is passing the pre-processed training data, consisting of 4000 patent descriptions classified binary (containing AI or not), which was published by Miric et al. (2023). For this thesis, each tree in the RFC is trained using the entirety of the patent dataset, ensuring that no information is discarded or overlooked.

Lastly, the now-trained RFC is applied to the EdTech dataset in question, resulting in a binary classification (AI or non-AI).

3.3 DATA ANALYSIS AND VISUALIZATION

Some of the columns deemed relevant in chpt. 3.1, were manipulated to enable a clear analysis. The information fields “Age” and “Age in days” were created based on “Founded Date”, and the field “Country” was derived from “Headquarters Location”. The “Country” field was further converted to 3 letter acronyms, following the international standard retrieved from the ISO (n.d.).

3.3.1 ADDITIONAL CONCEPTS UTILIZED IN ANALYSIS

To uncover the trends (“hot” or “cold” topics) central to the research question a statistical tool was employed. The kernel density estimate (KDE) is a technique in statistical analysis and data visualization, that offers a means to transform discrete data points into continuous estimates. This method produces a representation of data points as a smooth, continuous probability distribution. By doing so, a more nuanced understanding of the underlying data patterns is possible. KDE accomplishes this by placing a kernel at each data point and then summing these kernels to create a continuous probability density function. This transformation provides a richer visualization of data, facilitating the identification of peaks and overall data distribution characteristics. This thesis is a practical application of kernel density estimation for dealing with discrete data points. (Parzen, 1962; M. Rosenblatt, 1956; Scott, 1979).

The selected and transformed variables in this thesis were cross-evaluated by utilizing a correlation matrix. A correlation matrix provides a comprehensive view of how variables are interrelated, quantifying the degree and direction of these associations. Potential patterns, dependencies, and areas for further investigation are uncovered by displaying correlations as a matrix. This approach enables a deeper understanding of the dataset's structure. (Rencher & Schaalje, 2008, pp. 77–78).

3.3.2 VISUALIZATION TOOLS

The analysis and visualization in this thesis were executed using the Python libraries Seaborn (Waskom, 2021) and Matplotlib (Hunter, 2007). These tools are indispensable for data analysis and presentation, offering a rich array of functions and capabilities. Seaborn (Waskom, 2021), built on top of Matplotlib (Hunter, 2007), simplifies the creation of informative and aesthetically pleasing visualizations. Its diverse plot styles make it ideal for exploratory data analysis, while Matplotlib provides a versatile platform for fine-tuning and customizing

visualizations. Together, they offer a robust framework for researchers to dissect and communicate complex data patterns effectively.

4 RESULTS

This chapter lists the results obtained by the methodology described in the previous chapter and relationships to pre-existing facts are established.

4.1 AI ADOPTION IN THE EDTECH SECTOR

4.1.1 DEPLOYMENT OF AI DOES NOT FOLLOW A TEMPORAL TREND

Intended to reveal patterns in the adoption of AI technology within the EdTech market, the classification analysis of the data also sheds light on data quality aspects (see Fig. 8). It reveals intriguing patterns, particularly the striking coincidence of entry dates with the new year raises concerns regarding data quality. However, for the most recent years, the concentration around the new year is less pronounced. This improvement in data quality, suggests a maturation of data collection processes or an increased commitment to accuracy within the industry. This positive trajectory bolsters confidence in the reliability of the dataset, despite the initial temporal clustering.

Figure 4 Scatterplot Highlighting the ML-based Classification.

Furthermore, the analysis unveils an expected and unsurprising correlation between an organization's age and total funding. Large, well-funded entities consistently gravitate toward the upper-left quadrant of the classification, reinforcing that financial stability and organizational longevity are intrinsically linked in the competitive landscape.

Figure 5 Scatterplot Highlighting the Self-identified Classification.

Returning to the original focus, when exploring the spatial distribution of AI companies, the pattern appears random, without any visible clustering. This is true for both ML-based classification (see Fig. 4) and for self-identified classification (see Fig. 5). The RFC identified 1070 AI companies in the dataset, or approximately 7.6% of all firms. The dataset featured 496 self-identified AI companies, rounding out to 3.5% of all companies. In both cases, all the 14,046 entries in the dataset were assigned a classification.

The randomness of the spatial distribution of AI companies is proof that AI is currently not a “hot” topic in EdTech. Thus, RQ1 is rejected.

4.1.2 AI DOES NOT EMERGE AS A STAND-ALONE TOPIC

Topic Modeling using the BERTopic code library yielded 23 topics. 8352 entries out of the sample of 14046 companies could not be assigned to a topic and were thus excluded from further analysis. In most cases, their description was not specific enough (visible in the code in the appendix as the topic “-1_learning_students_platform_education”). These descriptions used mostly vague umbrella terms, like learning, students, platform, and education, that are commonly used throughout the entire corpus of company descriptions, thus they hold no relevant information for clustering. These words identify the company as a participant in the EdTech sector, they would hold meaning when clustering a more general sample of businesses but are useless when aiming to drill deeper within the sector. The size of a cluster or topic was set to a minimum of 100, resulting in a manageable number of topics for further evaluation. This in return also constitutes a reason for exclusion as smaller clusters were disregarded. The size of the topics ranged from 698 instances of “children_kids_parents_games” to 103 instances of “security_cyber_cybersecurity_services”.

Counter to the research question formulated at the beginning of this thesis, the topic of “Artificial Intelligence” did not occur, nor did any closely related verbiage, such as “Machine Learning” or “Large Language Model”, constitute a topic of its own. The absence of AI as a topic when clustering EdTech firms contained in a CB dataset suggests that entrepreneurs do not think of AI as a standalone business opportunity in the education space, certainly not when describing their companies. With regards to the research question, it is thus neither a “hot” nor a “cold” topic, as it is not an identifiable topic at all.

The information contained in the dataset also allowed for a temporal analysis of the topics. Using Kernel Density Estimation (KDE), the relative prevalence of a topic over time was visualized (see Fig. 5). This resulted in multiple leads that might constitute concrete insights when further drilled down.

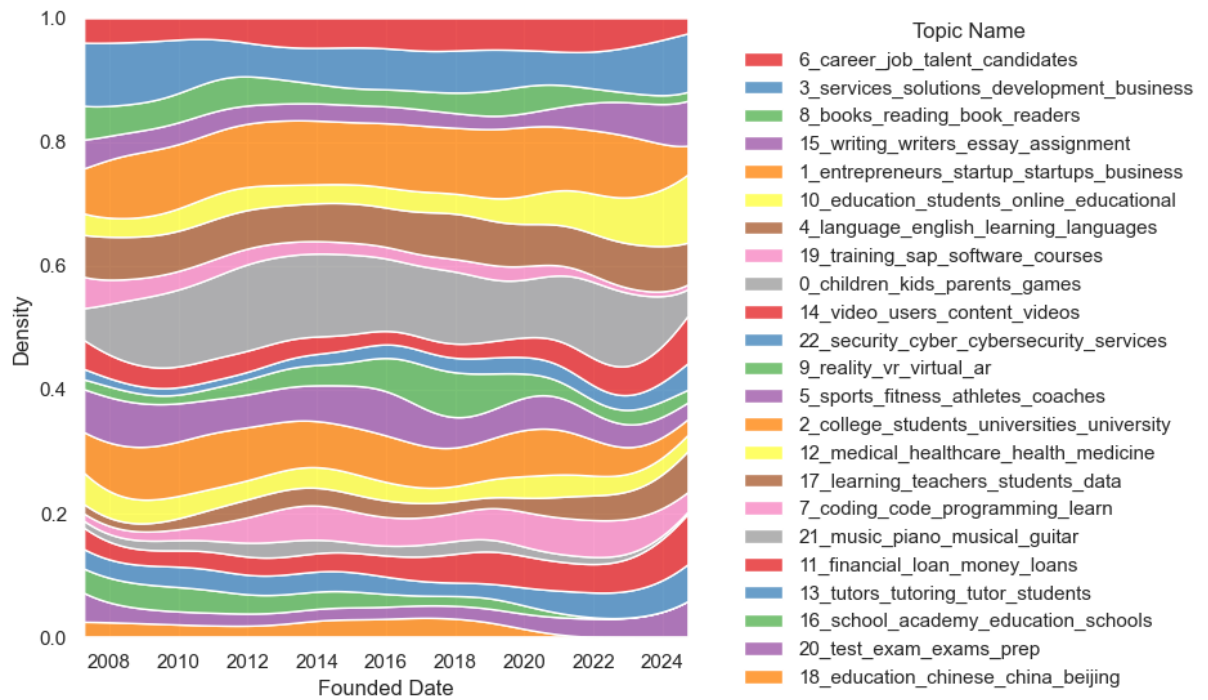

Figure 6 Kernel Density Estimate Indicating the Relevance of Topics Over Time.

Upon closer inspection, the trend estimates revealed one area of interest related to the adoption of AI. The promising anomaly is the growing number of ventures within the topic “15_writing_writers_essay_assignment” created after 2020. The increasing number of start-ups labeled “writing_writers_essay_assignment” in that period might be a proxy for LLMs as the technology rose to prominence for its text processing capabilities.

Given the insights based on KDE, subsampling topic 15 whilst also limiting the temporal scope of data to the years 2021 and 2022 seems promising. This temporal limitation coincides with the start-up definition (firm <2 years), thus general insights about start-ups can be found in the same analysis step.

The temporal limitations left 511 entries in the subsample, 9 thereof were assigned to topic number 15. Subsequent analysis revealed no heightened self-identification with the industry tag “Artificial Intelligence” in comparison with the overall dataset nor was the RFC AI tag more prevalent in this subsample. Therefore, Topic 15 cannot be considered a proxy for AI or LLM technology. Underlining again, that AI, even when considering proxy terminology is not a stand-alone topic in the EdTech market. Logically it can thus neither be “hot” nor “cold”.

Furthermore, the companies in topic 15 only amassed a mean funding of 24,182 USD. They underperformed both the whole dataset, coming in at 16,354,648 USD, which is to be expected as the ventures contained in the dataset are overall more mature, and their start-up peer group averaging 1,191,062 USD. The association with the topic “15_writing_writers_essay_assignment” proved not to be of advantage in fundraising.

The best-funded EdTech start-ups in the start-up subsample are focusing on university students, the only other start-up topic that attracted more than 2 million USD in funding on average is the topic “6_career_job_talent_candidates” encapsulating Human Resources related words (See Fig. 6).

Figure 7 Subsampling for Ventures (< 2 years)

In the final analysis step, the correlation between the NLP-based TM, the self-identified classification, and the ML-driven classification and the target variable of the total funding amount in USD is evaluated.

Figure 8 Correlation Matrix

The correlation matrix (Fig. 8) reveals a very low correlation for all analyzed output variables. This leads to the conclusion that in the EdTech sector based on the analyzed dataset, the association with AI does not correlate with successful fundraising. Thus, it can be concluded that association with AI does not in fundraising. Supporting the answer to research question one, that AI is not the “hot” topic in the EdTech sector, neither in terms of the number of firms established nor in funding allocation.

4.2 EMERGING TECHNOLOGIES IN EDTECH

The application of TM to the EdTech dataset yielded other valuable insights, not connected to AI. Based on KDE (see Fig. 6) topic 9, encapsulating verbiage connected to Virtual Reality (VR), offers a clear link to emerging technology. The firms associated with this topic might provide evidence of past “hot” topics in the EdTech sector.

4.2.1 TOPIC 9: VR – HOT TOPIC OF THE PAST

The interest in the wider digital economy outside the dataset surrounding VR and the metaverse peaked in October 2021, when The Facebook Company renamed itself to Meta (Meta, 2021). However based on the KDE analysis and following Blei, Ng, Michael, and Lafferty’s (2003) definition VR should be considered a “hot” topic during the years 2016-2019.

All VR ventures in the dataset received a mean total amount of funding of 7,531,751 USD, this is more than VR firms amassed during their “hot” phase where their relative number soared. The mean of 6,572,573 USD during the VR heydays is also less than the overall mean funding amount of 8,564,851 USD across the entire dataset in the same period (See Fig. 9). It appears that in the EdTech Market, an association with “hot” topics had a negative impact on fundraising in the past.

Figure 9 Mean Total Funding (in m USD) for VR Subsamples

This finding is in contrast with Cooper et. al (2001) who found a positive correlation between “hot” topics in technology and company valuation in US stock markets during the dot-com bubble. The answer to RQ2 is thus: The association with “hot” topics in EdTech does influence investor behavior. Its effect is negative on the amount of funding allocated.

4.2.2 TOPIC 18 AND TOPIC 16: CHINESE EARLY EDUCATION

The key variable used in this thesis to evaluate investor behavior is the total amount of funding received. The key variable is thus mapped and averaged to each topic (see Fig. 10). Even though the illustration uses a log scale for funding amounts topic 18 “education_chinese_china_beijing” is by far the best-funded topic.

Figure 10 Mean Total Funding per Topic.

Topic 18, the best-funded topic in the overall dataset was given up by founders in 2021 and is virtually inexistent thereafter. Based on the KDE (See Fig. 6) topic 16 seems to move in lockstep.

This striking observation is driven by regulation. The city of Beijing was a leader in banning tutoring for school-aged children, as the pressure put on by parents was seen as too taxing. Later in July 2021 the rest of China followed the example of its capital region. With the ban on tutoring digital offerings in the sector were made obsolete. (Feng, 2022a, 2022b). This regulatory change in China explains

the dramatic drop-off in relevance for topic 18 as a clear majority of 103 out of 137 firms are headquartered there and a further 6 firms have their HQ in the Chinese-speaking territories of Taiwan, Hong Kong, and Singapore.

Whilst the explanation for topic 18 is concise and clear, the opposite is true for topic 16. When analyzing the country of origin no striking pattern emerges, 101 of the 147 companies of topic 16 have their HQ in the USA, which can be considered inconspicuous given the remarks regarding data integrity and quality (see chpt. 3.1.2). This leaves two possible explanations: Either the firms served the Chinese tutoring market from outside the country, or the overlap is coincidental.

5 DISCUSSION

The subsequent chapter contextualizes the results of the NLP-based analysis of the dataset. Comparing the newly gained insights with pre-existing literature.

5.1 AI VENTURES IN EDTECH

The absence of AI as a topic when clustering EdTech firms contained in a CB dataset ranging from 2009-2022 suggests that entrepreneurs do not think of AI as a stand-alone business opportunity in the education space, certainly not when describing their companies. With regards to the research question, it is thus neither a “hot” nor a “cold” topic, as it is not an identifiable topic at all. AI is probably best seen as a tool. Referring to the four dimensions of the recombination school (Gassmann et al., 2014, 2016), it is a potential answer to the question of “WHY” or “HOW”, explaining the mechanisms within a business to achieve its goals. However, AI is not a common answer to the question of “WHAT” is the core of the offering or to the question of “WHO” is the target customer. But it is exactly the question of “WHAT” and “WHO” that are most pronounced in the company descriptions, given the overall verbiage of the labels.

A second plausible explanation for the absence of an identifiable AI cluster is that innovation in EdTech might be happening outside the traditional start-up space. This insight into the deployment of AI tools by established players is evident in other industries. For example, in the mining sector, the established player Volvo is using AI to automate mines. Further prominent examples include the deployment of AI in existing search tools by Google and Bing. The most clear-cut example of this line of thought is the integration of AI in Microsoft’s Office products, a business segment that was introduced in the late 1980s. Indeed, there is anecdotal evidence that established institutions are driving the integration of AI into the education sector. Harvard, for example, announced that its course CS50 will make use of AI-tutoring (Schisgall & Hamid, 2023). To further sharpen

and confirm this insight a study focusing on the integration of AI technology at higher education institutions is called for.

Lastly, there is also the possibility of a time lag of AI technology penetrating the education industry. The dataset might, simply put, only cover a period too early to contain a substantial number of AI-EdTech firms that would form an identifiable cluster. A repetition of the presented work at a later point in time is needed to confirm this hypothesis.

5.2 INVESTORS ARE NOT BLINDED BY HOT TOPICS

The idea of “hot” and “cold” topics applies to the EdTech market and corresponding phenomena are visible in the data analysis undertaken. The answer to the second research question thus is: The effect of the most striking “hot” topic “9_reality_vr_virtual_ar” on funding is negative. This evidence runs counter to the findings for public markets in the USA during the dot-com bubble, which inspired this thesis (Cooper et al., 2001).

A plausible explanation, as to why the effect is inversed is the idea of “smart money”. In the realm of finance and investment, the concept of “smart money” has gained prominence, reflecting a discerning approach to capital allocation. The market structure for private markets represented by the CB dataset is unlike the frenzied and speculative nature of the dot-com bubble in public markets. There is a distinction in investment behavior and strategies as the private market is marked by a more cautious and informed approach, with a focus on sustainable growth and value creation. Furthermore, the VC landscape, which plays a pivotal role in funding firms listed on CB, is predominantly staffed with professional investors. Institutional venture capitalists, family offices, and strategic investors favor due diligence and risk assessment over impulsive speculation. As noted in the theoretical background: work experience within the

financial industry reduces susceptibility to investment biases (Cronqvist & Siegel, 2014). This finding seems to be confirmed.

However, this thesis should not be interpreted as proof of the “smart money” concept. It is only evidence of the absence of trend-related bias in the specific and limited private market for EdTech.

6 CONCLUSION

In conclusion, this comprehensive analysis of a dataset containing 14,046 EdTech businesses has provided significant insights into the role of AI in this sector. Despite the prevalent discourse around AI as a transformative force in various industries, it appears that in the EdTech market, AI is not a primary focus but rather a tool employed to realize the visions of these companies. This observation is grounded in the absence of AI as a labeled topic among the 23 identified through topic modeling. The binary classification added in the second analytical step reaffirms that AI is not the current “hot” topic in EdTech. The distribution of AI companies concerning size, total funding, and age appears random, indicating no discernible trend towards AI. This lack of a clear trend made it impossible to analyze investor behavior regarding a trend-based bias linked to AI.

Furthermore, the temporal analysis using Kernel Density Estimates (KDE) revealed that VR was once a “hot” topic in the EdTech market. Interestingly, the association with this “hot” topic influenced investor behavior negatively. Ventures founded during the hype phase with growing interest in VR received less funding on average than both VR businesses across the entire dataset and the wider EdTech peer group founded within the same timeframe.

These findings challenge the notion of AI adoption as a dominant driver in venture creation within the EdTech market and highlight the importance of understanding the nuanced role of emerging technologies in shaping industry trends and investor behavior.

APPENDIX: NOTEBOOK PRINT-OUTS

Note: The complete code used in this thesis is also available under the following link:

<https://github.com/MarioMuehlematter/Education.ai>

The appended printed files are not as easy to reuse, and the PDF export generates separate page numbers.

Education.ai_Pre-Processing

Dataset Pre-Processing

Before starting the NLP-based analysis of the data, some general data-cleaning is in order.

Importing Libraries and Loading the Data¶

In []:

```
#import necessary lib
import pandas as pd
```

In []:

```
#load dataset
from google.colab import drive
drive.mount('1LbVccBPxo8pR9C4lwosD5qY0glKsDrPr')
```

Mounted at 1LbVccBPxo8pR9C4lwosD5qY0glKsDrPr

In []:

```
df =
pd.read_csv("/content/1LbVccBPxo8pR9C4lwosD5qY0glKsDrPr/MyDrive/001_Masterarbeit/2022-12-31_EdTech data set_raw.csv", index_col=0)
```

<ipython-input-4-c0ebe79655f4>:1: DtypeWarning: Columns (76,77,79,82,103,106,111) have mixed types. Specify dtype option on import or set low_memory=False.

```
df =
pd.read_csv("/content/1LbVccBPxo8pR9C4lwosD5qY0glKsDrPr/MyDrive/001_Masterarbeit/2022-12-31_EdTech data set_raw.csv", index_col=0)
```

First Look¶

In []:

```
df.info()
```

```
<class 'pandas.core.frame.DataFrame'>

As the list above indicates there are two columns labelled description (decription/ full description). Too keep as much information as possible filtering for NaN is run on both and the column with less invalid values is kept for further processing.

In []:

```
#convert descriptions to lowercase
df['Full Description'].str.lower()
df['Description'].str.lower()
```

Out []:

Organization Name

Name: Description, Length: 29346, dtype: object
```

```
In []:
```

```
#remove NaN values in description/ full description column and
establish temporary dataframes for comparison
temp1 = df[df['Full Description'].notnull()]
temp2 = df[df['Description'].notnull()]
```

```
In []:
```

```
temp1['Word Count'] = temp1['Full Description'].str.split().str.len()
temp2['Word Count'] = temp2['Description'].str.split().str.len()
```

```
<ipython-input-9-b2ec766b316c>:1: SettingWithCopyWarning:
A value is trying to be set on a copy of a slice from a DataFrame.
Try using .loc[row_indexer,col_indexer] = value instead
```

```
See the caveats in the documentation:
https://pandas.pydata.org/pandas-docs/stable/user\_guide/indexing.html#
returning-a-view-versus-a-copy
```

```
temp1['Word Count'] = temp1['Full
Description'].str.split().str.len()
<ipython-input-9-b2ec766b316c>:2: SettingWithCopyWarning:
A value is trying to be set on a copy of a slice from a DataFrame.
Try using .loc[row_indexer,col_indexer] = value instead
```

```
See the caveats in the documentation:
https://pandas.pydata.org/pandas-docs/stable/user\_guide/indexing.html#
returning-a-view-versus-a-copy
```

```
temp2['Word Count'] = temp2['Description'].str.split().str.len()
```

Filtering the Descriptions¶

Excluded companies whose descriptions are too short (word counts <30) to be useful for topic modeling, following the example of Chae & Olson (2021)

```
In []:
```

```
temp1 = temp1[temp1['Word Count'] >= 30]
temp2 = temp2[temp2['Word Count'] >= 30]
```

```
In []:
```

```
#essential summary statistics for the cleaned datasets
```

```
print('The dataset temp1 has ' + str(temp1.shape[0]) + ' entries.\n'+
      'The descriptions in the dataset contain a total of '+
      str(temp1['Word Count'].sum()) + ' words.')
print('The dataset temp2 has ' + str(temp2.shape[0]) + ' entries.\n'+
```

```
'The descriptions in the dataset contain a total of '+  
str(temp2['Word Count'].sum()) +' words.')
```

The dataset temp1 has 14046 entries.

The descriptions in the dataset contain a total of 1225060 words.

The dataset temp2 has 0 entries.

The descriptions in the dataset contain a total of 0 words.

All entries in the simple description column are too short, according to established data science practice. Therefore the 'Full Description' cloumn will be used for further NLP processing.

In []:

```
temp1['Word Count'].mean()
```

Out[]:

```
87.21771322796526
```

In []:

```
temp1['Founded Date'].min()
```

Out[]:

```
'01.01.09'
```

In []:

```
#export cleaned dataset  
from google.colab import files  
temp1.to_csv('2023-12-31_EdTech dataset_cleaned.csv')  
files.download('2023-12-31_EdTech dataset_cleaned.csv')
```

193d691028c548098375df8274fcfc4b

Analysing Company Descriptions using NLP

The goal is to represent each document (patent) based on the number of times each word occurs in them. We are going to use the Scikit learn (<https://scikit-learn.org/stable/index.html>) package, which has built-in functions that make this process very easy and straightforward.

This method has been proven to be the best performing in classifying patents mentioning AI by Miric, M., Jia, N. and Huang, K. (Forthcoming) Using Supervised Machine Learning for Large-Scale Classification In Management Research: The Case For Identifying Artificial Intelligence Patents. Strategic Management Journal.

Link: <https://www.milanmiric.com/ai-patents-us>

Convert Text Data to Term-Document Frequency Matrix:

We are going to use the built in sklearn tools to process the text. The idea is to construct a matrix representation of the data. The rows represent each document (patent abstract). The columns represent each word that occurs in any of the documents (corpus). The fields of the matrix (TF) represent how often each word occurs in each document.

This is illustrated below.

Topics worth investigating: Expansion in 10, 15, 17 Decreased interest in 8, 9 Complete drop-off in 16, 18, 19

Notes, possible Explanations:

8: Books -> market saturation, shrinking, unattractive market?

9: VR -> META effect? resp. market trend influencing META

10: online education -> Corona Boom

15: writing -> LLM integrations -> possible AI link

16: -> moves with 18, same explanation?

17: -> follows 10, learning moved online, better data availability

18: China banned education apps

19: Software training -> Market saturation?

Thus seems to rather follow macro-trends, than technological topics

#checking for corellation between analysed var and Total Funding
sns.heatmap(df[['Total Funding Amount Currency (in USD)', 'Class',
'Class self-identified', 'Topic']].corr(),
            annot= True,
            cmap = Set1_cmap
            )
plt.xticks(rotation = 45, wrap = True, ha = 'right')
plt.yticks(ha = 'right', wrap = True)
```

Out []:

```
(array([0.5, 1.5, 2.5, 3.5]),
 [Text(0, 0.5, 'Total Funding Amount Currency (in USD)'),
  Text(0, 1.5, 'Class'),
  Text(0, 2.5, 'Class self-identified'),
  Text(0, 3.5, 'Topic')])
```

No description has been provided for this image

very low correlation for all analysed variables (Topic, AI, AI self-described)

These var do not correlate with successfull fundraising, the idea of Cooper et al. could not be replicated for the EdTech market

DISCLOSURE OF DIGITAL TOOLS

Note: wherever possible the connected academic source was quoted (e.g. Bird, Loper, and Klein (2009) were cited in APA7 format in chpt. 3.2.2 instead of only specifying “nltk” in the following table)

<u>tool:</u>	<u>in-text location</u>	<u>usage:</u>	<u>cited:</u>
ChatGPT (GPT-3.5)	Full text	Generate draft based on key words: <u>Prompt schema:</u> “Draft a paragraph, ranging between 50 and 120 words in length, for an academic paper based on the following key insights: ****”	NO
Grammarly	Full text	Correcting spelling mistakes, suggest academic verbiage	NO
Pandas	3 Methodology, 4 Results, Appendix B	Data handling	NO

NumPy	3 Methodology, 4 Results, Appendix B	Mathematical functionality	NO
matplotlib	3 Methodology, 4 Results, Appendix B	Illustration	YES
seaborn	3 Methodology, 4 Results, Appendix B	Illustration	YES
google.colab	3 Methodology, 4 Results, Appendix B	Google cloud resources for topic modeling	NO

nltk	3 Methodology, 4 Results, Appendix B	Language processing	YES
BERTopic	3 Methodology, 4 Results, Appendix B	Topic modeling	YES
sklearn	3 Methodology, 4 Results, Appendix B	Machine learning	YES

DECLARATION OF AUTHORSHIP

I hereby declare,

- that I have written this thesis independently,
- that I have written the thesis using only the aids specified in the index;
- that all parts of the thesis produced with the help of aids have been precisely declared;
- that I have mentioned all sources used and cited them correctly according to established academic citation rules;
- that I have acquired all immaterial rights to any materials I may have used, such as images or graphics, or that these materials were created by me;
- that the topic, the thesis, or parts of it have not already been the object of any work or examination of another course unless this has been expressly agreed with the faculty member in advance and is stated as such in the thesis;
- that I am aware of the legal provisions regarding the publication and dissemination of parts or the entire thesis and that I comply with them accordingly;
- that I am aware that my thesis can be electronically checked for plagiarism and for third-party authorship of human or technical origin and that I hereby grant the University of St.Gallen the copyright according to the Examination Regulations as far as it is necessary for the administrative actions;
- that I am aware that the University will prosecute a violation of this Declaration of Authorship and that disciplinary as well as criminal consequences may result, which may lead to expulsion from the University or to the withdrawal of my title."

By submitting this thesis, I confirm through my conclusive action that I am submitting the Declaration of Authorship, that I have read and understood it, and that it is true.
